

PHP

- 1 - the browser requests a resource from the server that corresponds to a php script
- 2 - the server executes a php script
- 3 - the server responds to the browser with the requested data, which is typically in the form of an html document

the php interpreter is only capable of executing php code within the confines of its delimiters.

the primary objective of this approach is to effectively separate the php code from any non-php code, such as html

```
<? php echo 'hello world': ?>
```

or

```
<? 'hello world':>
```

number sqrt(num) : raiz quadrada
